How Waldur works

WALDUR

Waldur is an open-source platform between the people who use cloud, HPC and AI services and the infrastructure that runs them: one portal and API in front, every provider's services behind it.

Clouds with an API are provisioned directly. Clusters and services are run by the Waldur Site Agent at the provider's site, which only connects out to Waldur: no inbound ports, and the credentials stay on site.

What each part does

Portal and REST API

Users, providers and operators work in one web portal. Everything in it is also available through the REST API, with SDKs for Python and TypeScript, a command line tool, a Terraform provider, an Ansible collection and a built-in MCP endpoint for AI agents.

Identity

People sign in with the identity they already have: eduGAIN, eduTEAMS, MyAccessID, Keycloak, LDAP, SAML or a national service such as TARA. SCIM keeps users and groups in step with the identity provider.

Catalog and orders

Providers publish offerings with price plans. Customers order them for a project; an order can wait for approval by the project, the organization or the provider.

Organizations, projects and roles

Organizations own projects, people get roles in them, and roles can expire. Every change is recorded in an audit log.

Accounting and invoices

Fixed-price, usage-based, one-time and limit-based components are metered per resource and rolled up into monthly invoices, or exported to an external billing system.

Quotas and policies

Cost and usage limits per organization, project or offering. When a limit is reached, Waldur notifies the team, blocks new orders or requests downscaling.

Calls for proposals

Application forms, review rounds, conflict-of-interest checks and allocation decisions. Accepted proposals become projects with the awarded resources.

Support desk

Built-in tickets, or a connection to Jira Service Management, Zammad or OpenText SMAX, so customers have one support line for every service.

Connecting infrastructure

Clouds with an API (OpenStack, VMware vCenter, Rancher, another Waldur) are provisioned directly. Everything else runs through the Waldur Site Agent at the provider's site: Slurm, MOAB, Kubernetes, OpenNebula, Azure, DigitalOcean, LDAP, Ceph, Nextcloud, Harbor, LiteLLM and more. The agent only connects out to Waldur, so no inbound ports are opened and credentials stay on site.

Waldur is MIT-licensed. It runs as a Django backend and a React portal with PostgreSQL and RabbitMQ, deployed with Helm on Kubernetes or with Docker Compose.
